## INTRODUCTION

During the year 1971 the Steam-Electric project near Centralia, Washington will begin operation. This project has a potentially large capacity to cause water quality problems from several sources. Due to the lack of water quality information on the streams adjacent to the project (Hanaford Creek and its tributaries) it was apparent that some kind of surveillance program was necessary.

In May of 1970, the Washington State Department of Ecology established stations and began sampling the Hanaford Creek, and some of its tributaries in the vicinity of the Centralia Steam-Electric Project. Stations were also located on the Skookumchuck River above and below its junction with Hanaford Creek.

It is the purpose of this paper to report the results of the first year of sampling (May 1970 through April 1971). This data, along with some collected by the Washington State Department of Fisheries, will be used as background Water Quality to evaluate the effects of the coal mining, coal preparation, coal storage, and the power plant operation on the Hanaford-Skookumchuck River System.

## SAMPLING PROGRAM

<u>Station No.</u>	<u>Storet No.</u>	<u>Description</u>	<u>River Mile</u>
1	541206	Hanaford Cr nr Tono, Wash.	69.7-3.7-6.6
2	541207	Packwood Cr nr mouth nr Tono Wash.	69.7-3.7-5.7-0.3
3	541208	Overburden Cr nr mouth nr Tono, Wash.	69.7-3.7-5.2-0.2
4	541209	Hanaford Cr b1 Power Plant	69.7-3.7-3.8
5	541210	Hanaford Cr 0.2 mi ab S Hanaford Cr.	69.7-3.7-2.5
6	541211	S. Hanaford Cr 0.1 mi ab mouth	69.7-3.7-2.3-0.1
7	541212	N. Hanaford Cr at Tono, Wash.	69.7-3.7-2.0-4.7
8	541213	Skookumchuck R nr Centralia, Wash.	69.7-4.5
9	541214	Skookumchuck R at Centralia, Wash.	69.7-2.4

Samples were collected at the above stations (Fig. 1) twice each month, and returned to the Department of Ecology laboratory for analysis.

At each sampling staff height measurements were taken at stations 5 and 8, which are the United States Department of the Interior Geological Survey (U.S.G.S.) flow gaging station numbers 12-0265.5, and 12-0264.00 respectively. Flow measurements were then read from the current U.S.G.S. rating tables for these stations.

The Washington State Department of Fisheries had been collecting data on stations 1, 2, 3, 5, 7, 8 and 9. These stations were collected from June 1968 until December 1969. There was no set frequency, although there were 28 samplings during this 18 month period.

Several special stations are also shown in figure I. They were located as follows:

<u>Station No.</u>	<u>Description</u>
2A	Located on Packwood Creek approximately 1/4 mile from mouth of Packwood Creek and above the discharge from the Packwood Lagoon.
2B	Located in the discharge of Packwood Lagoon about 50 feet before it enters Packwood Creek.
10	Sampled from the test coal pile drainage. This was a floating station taken from the standing water around the coal pile.
11	Taken from standing water on the coal in the mining area just north of Overburden Creek and just east of Hanaford Valley Road.

#### METHODS

Commencing May 7, 1970, bi-monthly water samples were returned to the Department of Ecology laboratory for dissolved oxygen, conductivity, pH, turbidity, alkalinity and iron analysis. Dissolved oxygen was determined by the Azide modification of the Winkler Method. The dissolved

oxygen samples were taken to the manganic basic oxide state in the field, then returned to the laboratory, acidified and titrated with .025 N Sodium Thiosulfate reagent. The conductivity was run on a Leeds and Northrup conductivity bridge, and referenced to 25°C. Turbidity was conducted on a Hach model 2100A Turbidimeter, and pH on a Fisher pH meter. Total Alkalinity was titrated to a pH of 4.8 with sulfuric acid. Iron analysis was conducted on an Atomic Absorption Spectrophotometer, and is reported as total iron.

Total alkalinity, conductivity, pH and iron were recommended by Dr. Harold Lovell (State College Pennsylvania) as indicators of the effects of the mining and Power Plant Operation on water quality. Total acidity was also considered, but not included as one of the routine parameters because of difficulties in interpreting the results, although occasional samples were taken in the mine area and from the test coal pile drainage.

### RESULTS

The results of the Department of Ecology sampling from May, 1970 to April, 1971 are shown in the tables I through XI. A statistical summary of the information for this period of stations 1 through 9 is shown in table XII. Table XIII is a statistical summary of all data collected by the Department of Fisheries and the Department of Ecology from June, 1968 through April, 1971 (the Fisheries data is not included in this report).

On Station number 2 and 3, there were several dates when high turbidity, iron and conductivity values were obtained. These high values were caused by construction activities in the mining area. The dates of these occurrences were 9-8-70, 9-22-70 and 1-27-71. Although this data should not be included as background information, it does

indicate what could happen if adequate settling is not maintained on the surface drainage from the mining area. On 1-27-71, the company was painting some mining equipment with what appeared to be a primer containing iron compounds. This is the probable cause of the 16 ppm iron at station 3.

On 4-7-71 and 4-21-71, samples were collected at station 11 and a total acidity (boiling sample titrated to a phenolphthalein end point) was determined. On 4-7 the total acidity was 40 ppm and on 4-21 none could be measured. Samples collected by the Fisheries Department at station 10 had total acidity values as high as 66 ppm, (data not included on this report).

Two samples of washed coal, collected from the storage pile had mercury concentrations of 90 ppb and 93 ppb. Samples were also collected from the surface waters on April 2, 1971 for mercury analysis. The results of this sampling are reported in table XIV.

#### COMMENTS

1. There is some increase in iron, turbidity and conductivity values between station 1 (Hanaford Creek above the power plant) and station 4 (Hanaford Creek just below the site).
2. There is little change in water quality between stations 4 and 5.
3. Stations 2 and 3 show considerable variance in turbidity, total alkalinity and conductivity, but with the exceptions noted in the results, this appears to be natural.

4. The only parameter that was collected in the Skookumchuck River by Hanaford Creek is turbidity.
5. High total acidity values have been obtained from standing water on the coal in the mine and from the test pile, apparently related to amount of contact time the runoff water had with coal.

#### RECOMMENDATIONS

The sampling should continue at the same frequency through the start up and first year of the power plant operations. Sampling at stations 4, 6, 7, 8 and 9 can be discontinued. The parameters presently being collected appear to be adequate. The data should be evaluated after the power plant has been in full operation for at least one year.
